# Strategy to face the Direct Detection of WIMPs in the lab

We need very sensitive and radiopure Particle Detectors

Experiments have to be shielded against all possible backgrounds and profit from active background rejection techniques

Signatures of a Dark Matter interaction are required for a positive result

# Dark Matter Signal Signatures

Positive identification of WIMP against backgrounds

- Annual modulation
- Directionality of recoils

$$\eta(t) = v_{\oplus}(t)/v_0 = \eta_0 + \Delta\eta \cos\omega(t - t_0)$$

$$\frac{dR}{dE}(\eta(t)) \approx \frac{dR}{dE}(\eta_0) + \frac{\partial}{\partial \eta} \left( \frac{dR}{dE} \right)_{\eta=\eta_0} \Delta\eta \cos\omega(t - t_0)$$

$$S_k(t) = S_{0,k} + S_{m,k} \cos\omega(t - t_0)$$

# Annual Modulation

TASK 4

Small effect  
( $<7\%$  of  $S_0$ )

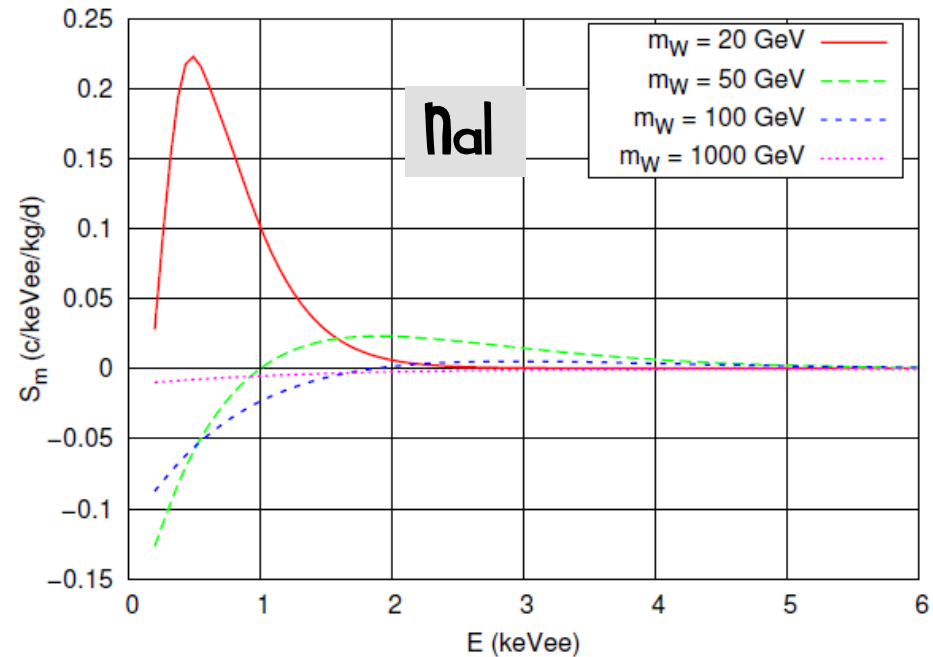

Figura 7.6: Ritmos de interacción en un detector de NaI el 1 de junio y el 30 de noviembre para diferentes masas del WIMP y  $\sigma_{SI} = 7,2 \times 10^{-6} \text{pb}$ . Podemos observar que tanto la amplitud de la modulación como su signo varían según la energía y  $m_W$ .

Inverse modulation at very low energies

$$\omega = 2\pi/365 \text{ d}^{-1}$$

$$t_0 \sim 1^{\text{st}} \text{ June}$$

$$S_k(t) = S_{0,k} + S_{m,k} \cos \omega(t - t_0)$$

# Dark Matter Signal Signatures

Positive identification of WIMP against backgrounds

- Annual modulation
- Directionality of recoils

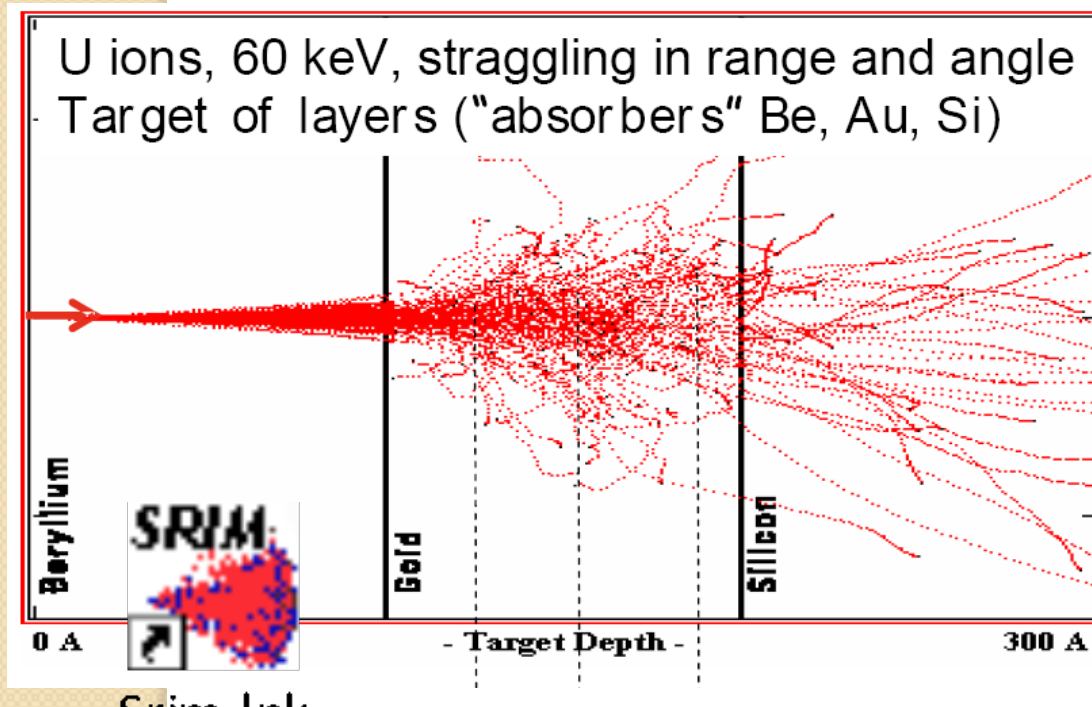

Fig. 1. The time averaged  $S$  recoil flux above 20 keV in Galactic  $(l, b)$  coordinates for the standard halo model, if the senses of the recoils can be measured and the uncertainty in the reconstruction of the recoil directions are included. The WIMP mass and cross-section are taken to be  $m_\chi = 100$  GeV and  $\sigma = 10^{-6}$  pb, respectively and the local WIMP density is  $\rho_0 = 0.3$  GeV  $\text{cm}^{-3}$ .

# Review of the Experimental Status

One single experiment has reported evidence of a signal compatible with Dark Matter observing a model independent annual modulation

DAMA/NaI-LIBRA Experiment

Other much sensitive experiments do not have any hint

**CONTROVERSIAL** issue

Is possible a model independent confirmation or refutation?

Make data public could have help?  
Are we prepared for unexpected results?

# Review of the Experimental Status

## DAMA/LIBRA experiment

~250kg NaI(Tl) scintillators @ LNGS

Total exposure:

DAMA/NaI (100 kg NaI, 7 years, completed in 2002)

+ DAMA/LIBRA (250 kg NaI, 7 cycles, ongoing)

→ **total exposure reported so far: 1.33 ton x year**

«Final model independent result of DAMA/LIBRA–phase1 » [arXiv:1308.5109](https://arxiv.org/abs/1308.5109)

# Review of the Experimental Status

## DAMA/LIBRA experiment

$$A_m = 0.0112 \pm 0.0012 \text{ cpd/kg/keV}$$
$$T = (0.998 \pm 0.002) \text{ y}$$
$$T_0 = (144 \pm 7) \text{ d (2}^{\text{nd}} \text{ June=153)}$$

No modulation above 6 keV

Evidence ( $9.3 \sigma$  C.L.) of an annual modulation of the *single-hit* events in the (2–6) keV energy region satisfying all the requests of a DM component in the galactic halo

### Total exposure:

DAMA/NaI (100 kg NaI, 7 years, completed in 2002)

+ DAMA/LIBRA (250 kg NaI, 7 cycles, ongoing)

→ total exposure reported so far: 1.33 ton x year

«Final model independent result of DAMA/LIBRA–phase1 » arXiv:1308.5109

# Review of the Experimental Status

## DAMA/LIBRA experiment Model Independent Result

$A_m = 0.0112 \pm 0.0012$  cpd/kg/keV  
 $T = (0.998 \pm 0.002)$  y  
 $T_0 = (144 \pm 7)$  d (2<sup>nd</sup> June=153)  
 No modulation above 6 keV

$$L_k = \prod_{ij} e^{-\mu_{ijk}} \frac{\mu_{ijk}^{N_{ijk}}}{N_{ijk}!} \quad (2)$$

**Total exposure:**  
 DAMA/NaI (100 kg NaI, 7 years, c  
 + DAMA/LIBRA (250 kg NaI, 7 cy  
 → **total exposure reported so far:**

«Final model independent result of DAMA/LI

where  $N_{ijk}$  is the number of events collected in the  $i$ -th time interval (hereafter 1 day), by the  $j$ -th detector and in the  $k$ -th energy bin.  $N_{ijk}$  follows a Poisson's distribution with expectation value  $\mu_{ijk} = [b_{jk} + S_{0,k} + S_{m,k} \cdot \cos \omega(t_i - t_0)] M_j \Delta t_i \Delta E \epsilon_{jk}$ . The  $b_{jk}$  are the background contributions,  $M_j$  is the mass of the  $j$ -th detector,  $\Delta t_i$  is the detector running time during the  $i$ -th time interval,  $\Delta E$  is the chosen energy bin,  $\epsilon_{jk}$  is the overall efficiency. The usual procedure is to minimize the function  $y_k = -2 \ln(L_k) - const$  for each energy bin; the free parameters of the fit are the  $(b_{jk} + S_{0,k})$  contributions and the  $S_{m,k}$  parameter.

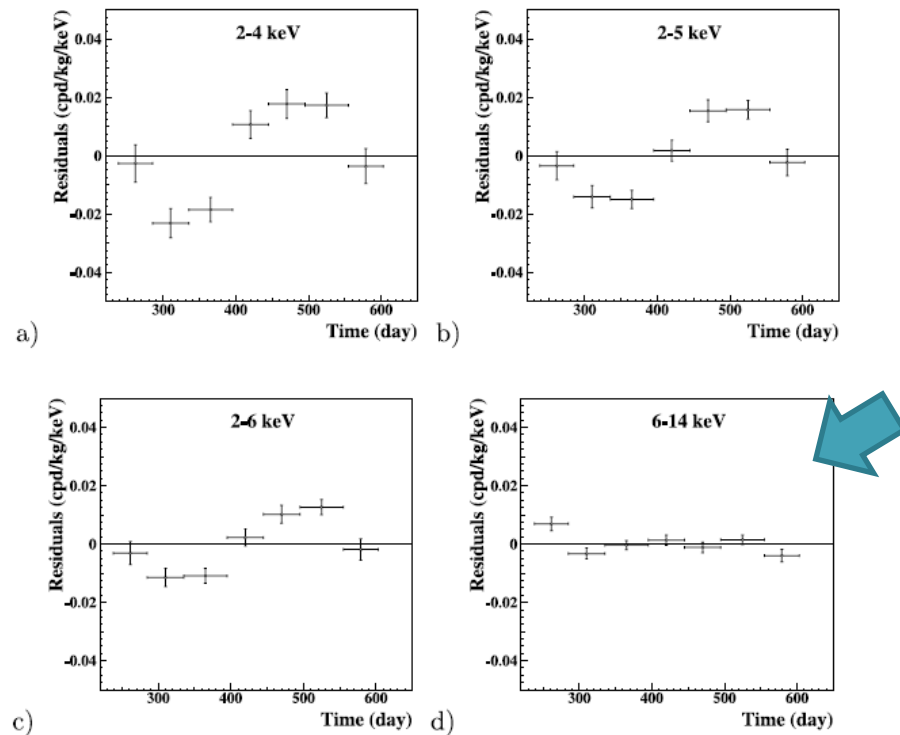

# Review of the Experimental Status

## DAMA/LIBRA experiment Model Independent Result

$$A_m = 0.0112 \pm 0.0012 \text{ cpd/kg/keV}$$
$$T = (0.998 \pm 0.002) \text{ y}$$
$$T_0 = (144 \pm 7) \text{ d (2}^{\text{nd}} \text{ June=153)}$$

No modulation above 6 keV

Evidence ( $9.3 \sigma$  C.L.) of an annual modulation of the *single-hit* events in the (2–6) keV energy region satisfying all the requests of a DM component in the galactic halo

part:  $\langle r_{ijk} - flat_{jk} \rangle_{jk}$ . Here  $r_{ijk}$  is the rate in the considered  $i$ -th time interval for the  $j$ -th detector in the  $k$ -th energy bin, while  $flat_{jk}$  is the rate of the  $j$ -th detector in the  $k$ -th energy bin averaged over the cycles. The average is made on all the detectors ( $j$  index) and on all the 1 keV bins ( $k$  index) which constitute the considered energy interval. The weighted mean of the residuals must obviously be zero over one cycle.

# Review of the Experimental Status

## DAMA/LIBRA experiment

## Model Independent Result

$$A_m = 0.0112 \pm 0.0012 \text{ cpd/kg/keV}$$
$$T = (0.998 \pm 0.002) \text{ y}$$
$$T_0 = (144 \pm 7) \text{ d (2}^{\text{nd}} \text{ June=153)}$$

No modulation above 6 keV

Evidence ( $9.3 \sigma$  C.L.) of an annual modulation of the *single-hit* events in the (2–6) keV energy region satisfying all the requests of a DM component in the galactic halo

Modulation disappears when looking at multiple hit events due to background

# Review of the Experimental Status

## DAMA/LIBRA experiment

## Model Independent Result

Average Rate at low energies at 1 evt/keV/kg day

Modulation amplitude decreasing till negative?

Figure 9: Energy distribution of the  $S_{m,k}$  variable for the total exposure (0.82 ton $\times$ yr, DAMA/NaI & DAMA/LIBRA). See text. A clear modulation is present in the lowest energy region, while  $S_{m,k}$  values compatible with zero are present just above. In fact, the  $S_{m,k}$  values in the (6–20) keV energy interval have random fluctuations around zero with  $\chi^2$  equal to 24.4 for 28 degrees of freedom. See also Appendix A.

# Review of the Experimental Status

# Review of the Experimental Status

DAMA/LIBRA experiment

Model Independent Result

## Ion Channelling

Fig. 1. Simplified schema of the channeling effect in the NaI(Tl) lattice. The axial channeling occurs when the angle of the motion direction of an ion with the respect to the crystallographic axis is less than a characteristic angle,  $\psi_c$ , depicted there (see for details Sect. 2). Two examples for channeled and unchanneled ions are also shown (dashed lines)

Still some things to understand better

Anomalous very long ion penetration in crystalline targets when inciding in the direction of a symmetry axis or plane

Small angle scattering maintains the ion the open channel

Channeled ions loose their energy predominantly to electrons  
more scintillation light in NaI Tl for nuclear recoils channeled

# Review of the Experimental Status

**DAMA/LIBRA experiment**

**Model Independent Result**

**Quenching Factor**

Colaboración	Q	
	Na	I
UKDMC	0,31 $0,275 \pm 0,018$	0,09 $0,086 \pm 0,007$
DAMA	0,30	0,09
Saclay-NaI	$0,25 \pm 0,03$	$0,08 \pm 0,002$
ELEGANTS V	$0,4 \pm 0,2$	$0,05 \pm 0,02$

Still some things to understand better

Non negligible uncertainties in the relative efficiency factor for nuclear recoils vs electron recoils

In the case of NaI detectors in the search for Dark Matter we have to know recoil energy scale for Na nuclei and I nuclei and are very different

# Review of the Experimental Status

**DAMA/LIBRA experiment**

# Review of the Experimental Status

## DAMA/LIBRA experiment

## Comparison with other experiments

Many WIMP scenarios considering halo and particle models have been considered and reconciling experiments seems very difficult

**VERY EXCITING CHALLENGE FOR PHYSICS IF TRUE!**

In order to decouple **unknown and uncertainties** from particle, astronomical and nuclear models we should combine:

- Different detection techniques
- Different target materials
- Different signal signatures

*The race to detect dark matter has yielded mostly confusion. But the larger, more sensitive detectors being built could change that picture soon.*

Millisecond pulsars could explain it

# Searching for excess from dwarf galaxy satellites

Fermi-LAT, arXiv:1503.02641 [astro-ph.HE]

# Searching for lines

- 3.7 years of data
- 5 ROIs:
  - R3 (NFW Optimized)
  - R16 (Einasto Optimized)
  - R41 (NFW Optimized),
  - R90 (Isothermal Optimized)
  - R180 (DM Decay)

**No evidence found!**

DM-t

D. Cerdeño lessons

# Evidence for 130 GeV line ?

43 months Fermi LAT data +  
new adaptive procedure to select optimized target regions depending on the profile of  
the Galactic dark matter halo.

Signal  
particularly  
strong in 2  
of the 5  
analyzed  
sky regions

Possible systematic effects involved  
Similar line appears in limb view  
Statistics of the evidence under question

# Gamma Background spectrum

Di Mauro, Donato, *Phys.Rev. D* **91**, 123001 (2015)

## • Annihilation

- Stringent constraints although with relatively large uncertainty (PASS 7)

## • Decay

- Stringent constraints (better than dwarf galaxies and galaxy clusters)
- Interesting implications for phenomenological models that address positron excess found with PAMELA and AMS-02

# 3.5 keV X ray line

73 galaxy clusters (XMM-Newton, center)  
 Perseus cluster (Chandra, center)  
 Virgo cluster (Chandra, center)

Line found in spectra from galaxies and galaxy clusters

Still controversial  
 possibility of atomic line  
 or instrumental systematics

M31 galaxy (XMM-Newton, center & outskirts)  
 Perseus cluster (XMM-Newton, outskirts)

Could be produced by the decay of sterile neutrinos

# Atmospheric Cerenkov Detectors

The atmosphere is the detector

# CTA

- Chile and La Palma locations
- $\text{km}^2$  array of Atmospheric Cherenkov telescopes
- Energy coverage from a  $\sim 10 \text{ GeV}$   $\sim 10 \text{ TeV}$
- Angular resolution as low as  $0.02^\circ$

# Atmospheric Cerenkov Detectors

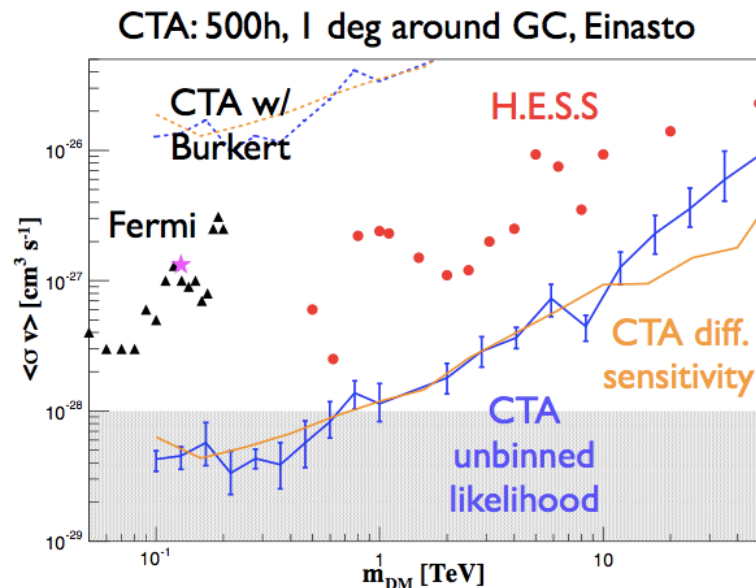

TeV dark matter is motivated by LHC negative results on SUSY and will be reachable by CTA

# Atmospheric Cerenkov Detectors

## Sensitivity for different targets

Good prospects for the galactic center

500h, WW / bb, different targets

Sensitivity to gamma ray lines

Anomalies have produced a continuous improvement in sensitivity of  $DM$  detectors and techniques

Most of these anomalies are expected to disappear very fast

Others do not

... like DAMA LIBRA

Next decade could be crucial to find the solution LHC CTA LZ SUPERCDMS XENON1T,

...

Hopefully in the next decade the multimessenger approach will succeed to solve the dark matter problem
